ABSTRACT

Alterations in the levels of oxidative stress and haemostatic markers have been proposed as one of the mechanisms for obesity-related cardiovascular disease. This study aims to evaluate the effect of 12-week behavioral lifestyle modification program on the oxidative stress levels in obese subjects. This is an interventional prospective study conducted from April 2009 through December 2010. Thirty four obese adult recruited from the Obesity Clinic, Hospital Universiti Sains Malaysia participated in the 12-week behavioral lifestyle modification program consisting of diet and exercise interventions. Body weight, BMI and body fat were significantly reduced after 12-week interventions. Plasma GPx activity and 4-HNE concentration increased significantly after 12-week interventions. Other enzymatic antioxidant activities such as CAT and SOD increased, and GSH:GSSG ratio reduced but the changes were not statistically significant. Plasma fibrinogen, factor VII, TAFI, t-PA and PAI-1 levels were significantly decreased and plasma Heparin Cofactor II level was significantly increased after 12-week intervention. In conclusion, diet and exercise interventions reduce cardiovascular risk factors by reducing body fat, increasing enzymatic antioxidant defense and beneficially altering the levels of haemostatic markers in obese adults.

Key words: *cardiovascular disease, obesity, oxidative stress, haemostatic markers, exercise, dietary intervention*

ABSTRAK

Perubahan dalam tahap stres oksidatif dan penanda haemostatik telah dicadangkan sebagai salah satu mekanisme untuk penyakit kardiovaskular berkaitan obesiti. Kajian ini bertujuan untuk menilai kesan program 12-minggu pengubahsuaian tingkah laku gaya hidup terhadap tahap stres oksidatif dalam subjek obes. Ini merupakan kajian prospektif intervensi yang dijalankan dari April 2009 hingga Disember 2010. Tiga puluh empat orang dewasa obes yang direkrut dari Klinik Obesiti, Hospital Universiti Sains Malaysia mengambil bahagian dalam 12 minggu program pengubahsuaian tingkah laku gaya hidup yang terdiri daripada diet dan senaman. Berat badan, BMI dan lemak badan telah dikurangkan dengan ketara selepas intervensi selama 12 minggu. Aktiviti plasma GPx dan kepekatan 4-HNE meningkat dengan ketara selepas intervensi selama 12 minggu. Lain-lain aktiviti antioksidan enzim seperti CAT dan SOD meningkat, dan nisbah GSH:GSSG dikurangkan tetapi perubahannya tidak ketara secara statistik. Tahap plasma fibrinogen, faktor VII, TAFI, t-PA dan PAI-1 menurun dan plasma heparin kofaktor peringkat II meningkat dengan ketara selepas intervensi selama 12-minggu. Kesimpulannya, intervensi diet dan senaman mengurangkan faktor risiko kardiovaskular melalui pengurangan lemak badan, peningkatan pertahanan antioksidan enzim dan perubahan tahap penanda haemostatik secara berfaedah dalam orang dewasa obes.

Kata kunci: penyakit kardiovaskular, obesiti, stres oksidatif, penanda haemostatik, senaman, intervensi diet
