ACKNOWLEDGEMENT

I would like to express my gratitude towards the Most Gracious and the Most Merciful, Allah SWT for giving me the chance, granted with a good health and capability to finish this thesis.

I would like to address my debt and appreciation to the management of Universiti Sains Malaysia, for the opportunity to complete this four year course of mechanical engineering.

I would also like to express my gratitude towards Dr Khairil Faizi Mustafa, my dedicated supervisor who has been guiding me throughout this project. Greatest thanks for the opportunity given to undertake this final year project and for the endless help that was provided in finishing this project.

Also to the staffs of School of Mechanical Engineering for their fullest support. Their assistant and cooperation in making this project a success was much appreciated.

Not to forget, I would like to thanks all my friends and fellow families who have given me endless support and encouragement throughout this project. The continuous contribution either mentally, or physically, I'll accept with greatest thanks.

SISTEM PENJANAAN KUASA TERMOELEKTRIK BEDASARKAN PEMBAKARAN BAHAN API CECAIR MELALUI MEDIA BERLIANG

ABSTRAK

Projek ini membentangkan sistem penjanaan kuasa termoelektrik yang menggunakan bahan api cecair yang dinyalakan melalui media berliang. Tujuan kajian ini dijalankan adalah untuk menguji kebolehan modul termoelektrik terbabit untuk menjana tenaga elektrik berdasarkan haba yang dihasilkan oleh pembakaran bahan api cecair. Sistem ini menggunakan kerosin sebagai bahan api, dibakar dengan pelbagai nisbah setara bahan api-udara diantara $\emptyset = 0.813$ hingga $\emptyset = 18.227$. Suhu hasil dari pembakaran disukat menggunakan alat pengimejan haba, manakala, kuasa yang dijana oleh modul termoelektrik disukat menggunakan multimeter dan dikenalpasti bahawa di nisbah kesetaraan bersamaan dengan satu, modul termoelektrik mampu menjana kuasa tertinggi, iaitu P = 1.056 W dengan purata suhu, T = 437.25 °C. Kuasa yang dijana di kawasan kekurangan bahan api dengan nilai $\emptyset = 0.183$ ialah P = 0.602 W dengan purata suhu T = 425.04 °C. Manakala kuasa yang dijana di kawasan yang kaya bahan api dengan nilai $\emptyset = 2.036$ ialah P = 0.293 W dengan purata suhu T = 500.62 °C. Ianya telah dikenal pasti bahawa, pada nilai $\emptyset = 1$, kuasa yang mampu dijana adalah maksima, manakala dengan nilai Ø yang lebih besar atau kecil, kuasa yang dijana akan semakin berkurangan. Walaubagaimanapun, suhu yang disukat didapati semakin meningkat dengan meningkatnya tempoh waktu pembakaran. Justeru, prestasi sistem penjanaan kuasa termoelektrik telah dinilai dan diperolehi di kedua belah kawasan kekurangan dan kaya dengan bahan api.

THERMOELECTRIC POWER SYSTEM FROM A LIQUID-FUELED-FIRED POROUS BURNER

ABSTRACT

This project presents a set up of a thermoelectric power system that uses liquid fuel, fired through a porous media burner. The aim of the study is to evaluate the capability of the thermoelectric module to generate electricity based on the heat produce by the combustion of the liquid fuel. The system uses kerosene as a fuel, combust with variety of equivalence ratio between $\emptyset = 0.813$ to $\emptyset = 18.227$. Heat as the product of the combustion is measured using a thermal imager device, and the power generated by the thermoelectric module is measured using multimeter and it is found out that at an equivalence ratio equal to one, the module generate the highest power, where P = 1.056 W with average temperature of T = 437.25 °C. The power generated at fuel-lean region with $\emptyset = 0.813$ is P = 0.602 W with average temperature T = 425.04 °C. Whereas the power generated at fuel-rich region with $\emptyset = 2.036$ is P = 0.293 W with average temperature of T = 500.62 °C. It is found out that the highest power generated can be obtained at $\emptyset = 1$, and the power generated decrease with lower or higher value of Ø. However, the measured temperature is found out to increase with increasing period of combustion. Hence, the performance of the thermoelectric power generating system is evaluated and achieve at both fuel-lean and fuel-rich region.

CHAPTER 1 INTRODUCTION

1.1 Research Background

Liquid fuel combustion has been widely used for transportation and power generation applications because of their high fuel efficiency. However, the process of combustion produces large amount of heat that is not being used by the system. Taking the heat produce by an automobile as reference, statistically, 40% of the heat generated is release to the atmosphere through the exhaust (He, Wang, & Yang, 2016) and 6% of these heat can be converted into electrical power resulting in about 10% reduction of fuel consumptions (Vázquez, Sanz-Bobi, Palacios, & Arenas, 2002). This is made possible with the use of thermoelectric (TE) devices where electrical energy is generated when heat flows through the semiconductor material due to the temperature gradient between the hot and cold junctions (Mustafa, Abdullah, Abdullah, & Sopian, 2017).

In general, Thermoelectric (TE) module is a device that is capable to produce electricity due to the temperature difference between the hot and cold junction(Zheng, Liu, Yan, & Wang, 2014). TE modules converts thermal energy directly into electrical energy(Qiu & Hayden, 2012). Nevertheless, the efficiency of TE devices are relatively low. The efficiencies however depends on various methods of fuel-air mixing processes, fuel-air equivalence ratio, and thermal and combustion characteristics. Among these, fuel-air mixture role is significant for TE power devices(Mustafa et al., 2017).

1.2 Problem Statements

The thermoelectric (TE) module main purpose is to generate electric energy by converting heat energy into electrical energy. Therefore, the main focused of the present paper is to investigate the generated power output of the TE system via liquid fuel combustion through porous burner. The primary aim of the study is to understand the influence of air-fuel equivalence ratios towards the performance of the TE system. Difference air-fuel equivalence ratio would lead to either fuel-lean or fuel-rich combustion. Hence, by knowing the optimum electricity produce by the TE module in either condition, we can assume which is the best for the TE module to operate.

1.3 Objectives

- 1. To determine the heat flow on the combustion chamber.
- 2. To evaluate the effect of porous burner and air-fuel mix ratios.
- 3. To measure the electrical energy generated by the thermoelectric system.

1.4 Scope and Limitations

There are several scope of work to accomplish the objectives of this paper. The parameter of this work started with studying the design of previously fabricated combustion chamber as to understand how would the combustion chamber operate and hence prepare the combustion chamber for the experiments. Then, from the combustion of the fuels, flame changes and heat produced by the combustion will be investigated in various value of equivalence ratios. This is to evaluate the effects of equivalence ratios towards the flame formations and heat production by the combustions.

Next is to simulate the combustion process occurred in the combustion chamber as to study the heat flow in the combustion chamber, and approximate temperature gradient of the combustions. Then, the results will be compared with the experimental results.

Last but not least, the thermoelectric module will be tested with the combustions of the fuels. The results of voltage, current and power generated by the thermoelectric module will be evaluated.

CHAPTER 2 LITERATURE REVIEW

Based on the research done by (Liu & Zhong Li, 2013) the system could achieve maximum power output with varying temperature difference, ΔT . In their paper, water– cooling method is proposed to keep the temperature difference between the hot and cold junction. Forty-eight aluminium cooling plates are used as thermal spreader to provide uniform temperature and pressure distribution across the TE module. Whereas for the hot junction, electric heating rod is chosen, heating a flat structure with conducting oil filling the cavity of the structure. Figure 2-1 and Figure 2-2 shows the layout of both cold and hot junction.

Figure 2-1 Installation of both cold junction onto TE module

Figure 2-2 Installation of hot junction onto TE module

Based on their experiment, a trend of increasing value of power output with respect to increasing value of ΔT is observed. Figure 2-3 and Figure 2-4 shows the trend of power output and voltage output with increasing value of ΔT .

Figure 2-3 Plot of power output against ΔT

Figure 2-4 Voltage output against ΔT (right)

However, at high temperatures, there are deviations between predicted value of power output from the TE module. This is due to the fact that not all heat from the hot side is absorbed by the TE module. There is a limit to which amount of heat that is capable to be absorbed by the TE module. A suggestion to improve this condition is by installing multiple TE module across the hot and cold junction as to improve the amount of heat being absorbed rather than radiates into waste.

Whereas from the reasearch done by (Xiao, Qiu, Gou, & Ou, 2013) a research was done to investigate several condition that may increase the output of thermoelectric generator, TEG. In their research, they developed a flameless catalytic combustion-based TEG. Natural gas was used for the combustion inside the chamber. In order to establish appropriate temperature difference, three large heat sinks was used to surround the chamber, which the cold sides of the TE module are fixed. Figure 2-5 shows the layout of the combustion chamber.

5-Porous metal plate (catalytic reaction layer) 6-Combustion chamber 7-Nozzle 8-Natural gas tube

Figure 2-5 The overall overview of the combustion chamber

It was found that the TEG can perform better with uniform heat distribution towards the TE module. In the test, indirect heat from the combustion is used. The TE module has the advantage from the natural gas combustion inside the chamber. This has left the system with nonuniformed heat distribution. Thus, by having a direct combustion heat to be absorbed by the TE module, lower time to achieve stability and uniform heat distribution across the TE module can be obtained. In other work that have been done by (Li, Chao, & Dunn-Rankin, 2008) a stable flame of combustion can be obtained by using a porous media burner. In their experiment, they tested the combustion of fuel in porous burner with different material and sizes. Based on their findings, different type of material produces stable flame at different air flow. This is due to the thermal conductivity and thermal diffusivity of the material. The thermal conductivity of the porous medium would influenced fuel vaporization rate, hence effects the combustion phenomena in the chamber. With different air flow rate and bead sizes, the flame of the fuel combustion doesn't change drastically. Figure 2-6 shows the stability of flames under different value of air flow rate and bead sizes.

(The small box to the right is enlarged view near a porous medium)

A smaller stable operation range was achieved with larger bead sizes. This is due to the relatively lower thermal conductivity and thermal mass, hence the ability to absorb heat from the flame for fuel vaporization is lower compared to smaller beat sizes porous medium. Moreover, the fuel spread for larger beat size is dominated by external flow rather than capillarity. This cause the larger bead size combustor to be more sensitive towards external pertubation. Figure 2-7 shows that larger bead size medium have smaller stable operational range whereas Figure 2-8 shows the exit temperature distribution of combustor with difference bead size and air flow rate. It shows that the heat release is dependant on the bead sizes.

Figure 2-7 Stable operational envelopes for combustor with different bead sizes (bronze).

Figure 2-8 Temperature distributions at the combustor exit for different bead sizes.

Next, from the work done by (Rana, Date, Iqbal, & Akbarzadeh, 2019), they have simulate an optimization of a thermoelectric generator power system. Their model uses 50 TEG modules, placed in between a hot water channel and a cold water channel. The TEG properties and waste heat properties are set as the fixed input. Whereas the variable input consist of the flow rate, gap height, and also the length and width of the heat exchanger. Their proposed model is capable to predict gross power, nett power, and pumping power for all operating conditions. Their simulation runs with hot side temperature, $T_h = 90^{\circ}$ C and the cold side temperature of of $T_c = 15^{\circ}$ C, flow rate varies from 1 l/min to 300 l/min and gap height of 1 mm to 3 mm. Thermal resistance and efficiency of the TEG modules is considered as 0.72 (°C/W) and 1.91% respectively. Figure 2-9 shows the maximum net power, respective gap height and flow rate.

Length (m)	Width (m)	Gap height (mm)	Flow rate (L/min)	Net Power (W)
2	0.04	15	46	76.15
1	0.08	9	56	77.97
0.4	0.2	6	92	78.79
0.2	0.4	5	153	78.97
0.08	1	4	300	79.02
0.04	2	2	289	78.66

Figure 2-9 Possible combinations for 50 modules gap height, flow rate to get maximum power

The maximum power output of 79.02 W is obtained at the combination of 0.08m long, 1m wide, 4mm gap height and 300 l/min flow rate. Figure 2-10 below shows the plot of power generated by the TEG modules.

Figure 2-10 Gross power, net power, and maximum net power

Whereas for the effect of number of modules on power generated, a number of simulations have been done using 50, 100, 500, 1000, 2000, 5000, and 10000 combinations of TEG module. The condition for this simulation is that the flow rate is considered 6 times to the number of TEG module, varied gap height of 1mm to 30mm, $T_h = 90^{\circ}$ C, $T_c = 15^{\circ}$ C, TEG efficiency of 1.91% and thermal resistance of 0.72 °C/W.

The absolute gross power and maximum net power per module of different number of TEG sets used is shown in Figure 2-11 below.

Figure 2-11 Absolute gross power and maximum net power for different size of power generation system

Figure 2-11 also shows the power losses due to convective and conductive thermal resistance and pumping power losses. From this work, the theoretical model has shown that combinations of varying parameter would produce various amount of generated power. However, this work role with the temperature difference between a channel of hot water and a channel of cold water only.

CHAPTER 3 METHODOLOGY

3.1 Experiment Flow Chart

6

From the flow chart, the full set up of the combustor is firstly done. The flow of combustion start off with air being supplied to the chamber, followed by the fuel that is gravitationally fed onto the porous media burner that is placed in the center of the combustor. The combustion is then ignited by using lighters that provide initial heat for the combustion to occur. The temperature of the porous media burner is recorded using the thermal imager. All result are tabulated.

3.2 Procedure of Experiment

First, the required material and components were prepared. This includes the air flow supply, anemometer, combustion chamber, liquid kerosene, thermal imager, multimeter and thermoelectric module.

Figure 3-1 Full setup of the experiment

Figure 3-2 Full setup of the experiment

The air flow was controlled by adjusting the velocity of air. Anemometer was used to read the velocity of the compressed air. The outlet from the compressed air supply was connected to the air flow inlet in the combuster via the coupling adapter.

Figure 3-3 Air flow inlet connection (a) and the coupling adapter (b)

Then fuel was weight to measure the initial mass of the fuel before the combustion. The fuel was then poured into the fuel tank. The fuel was fed into the combustion chamber via a throttle. The throttle was adjusted to release the desired amount of fuel into the combustion chamber.

Next, the combustion was ignited inside the chamber. A lighter and a piece of paper was used to introduced heat to the porous media burner. Once the combustion started, the chamber was let to burn for around five to ten minutes. The time for combustion was measured and recorded. Then, the thermal imager was used to measure the temperature at the center of the porous media burner. Data of the temperature of the porous media burner was recorded.

Then the thermoelectric stand was placed on top of the chamber, followed by the thermoelectric module that was placed on top of the stand. The sets of thermoelectric module was connected in series where the end wire was connected to a multimeter. The red end wire was connected to the red probe and the black end wire was connected to the black probe. The voltage and current produce by the thermoelectric module was measured using the multimeter and recorded.

The steps were repeated using various values of air flow rate and fuel flow rate. The air flow rate used was 10, 20, 30, 40, and 50 l/min whereas the fuel flow rate was adjusted for 5 types of openings. This combination of fuel openings were repeated for all five type of air flow rate used.

The data obtained from the experiment were tabulated and analyse. Power generated by the thermoelectric module was calculated by the equation of power, P = VxI, where V is voltage and I is current. Several graphs were then plotted which include, Temperature, T against Air Fuel Ratio, A/F_{ratio}, Temperature, T against Equivalence Ratio, Ø, Current, I agaisnt Voltage, V and Power, P against Equivalence Ratio, Ø.

3.3 Combustion Calculation

Most of the liquid fuels available are the combinations of hydrocarbons with varying number of carbon and hydrogens atoms. Generally, liquid fuel hydrocarbons is summarize as a single hydrocarbon with an empirical formula of CxHy. Most commonly used hydrocarbon includes gasoline, diesel, and kerosene. In this experiment, kerosene is used and a molecular number of $C_{12}H_{23}$ is assumed. Kerosene is obtained via fractional distillation of petroleum between 150 and 275°C, which produce clear liquid with low viscosity composed of carbon chains typically between 10 to 16 carbon atoms per molecule.

When a liquid fuel is reacted with oxygen, heat is generated as a product of the reaction and this heat can be harvested to be used for various purposes. This process is known as combustion. When liquid fuel reacts with pure oxygen, it gives out products and heat. Thus, the process will always be exothermic as heat is release from the reaction. The general chemical reaction of liquid fuel reacting with pure oxygen undergoing combustion can be written as:

$$Fuel + O_2 \rightarrow Products + Heat$$

The products of the combustion consists of carbon dioxide, CO_2 and water, H_2O Wheras for kerosene,

$$4C_{12}H_{23} + 71O_2 \rightarrow 48CO_2 + 46H_2O_2$$

The amount of air that is used to complete the combustion is known as stoichiometry, or theoretical air. Stoichiometry air is used completely in a combustion process without excess air or excess fuel in the end.

Whereas for an incomplete combustion, there are either excess air, or excess of fuels. The condition where air is in excess is referred as lean combustion and the condition where fuel is in excess is known as rich combustion. The general combustion of liquid fuel with pure air can be written as:

$$C_x H_y + v_{O_2}(O_2 + 3.76N_2) \rightarrow v_{CO_2} CO_2 + v_{H_2O} H_2O + v_{N_2} N_2$$

Balancing the atoms as to achieve a complete combustion, or also known as clean combustion, would results in obtaining the amount of theoretical air for the combustion. The outcome value of the coefficients is known as stoichiometric coefficients. For stoichiometry balancing,

- C: $V_{CO2} = x$
- H: $2(V_{H2O}) = y$

 $N_2: V_{N2} = 3.76(V_{O2})$

 $O_2: V_{O2} = V_{CO2} + V_{H2O}$

2 = x + y/4

Thus the total number of moles of air for 1 mole of fuel becomes

 $n_{air} = V_{O2}(4.76) = 4.76(x+y/4)$

In real application, the parameters used to obtained either lean or rich combustion are either air fuel ratios, A/F_{ratio} or the fuel air ratio, F/A_{ratio} . These ratios can normally be controlled in an application. Both air fuel ratio and fuel air ratio are defined as,

$$A/F_{ratio} = \frac{\dot{m}_a}{\dot{m}_f}$$
$$F/A_{ratio} = \frac{\dot{m}_f}{\dot{m}_a}$$

In terms of mole,

$$A/F_{ratio} = \frac{n_a}{n_f}$$
$$F/A_{ratio} = \frac{n_f}{n_a}$$

From these A/F_{ratio} , the equivalence ratio can be found. The equivalence ratio can be used to identify either lean or rich combustion occurred. The equivalence ratio is given as,

Equivalence Ratio,
$$\phi = \frac{A/F_{stoichiometry}}{A/F_{actual}}$$

A/F_{stoichiometry} is the chemically correct air fuel ratios that would satisfy a complete combustion. Hence, for \emptyset =1, the combustion is said to be in stoichiometry, where no excess air or fuel is present. For \emptyset <1, the combustion is in the lean region, with exces air, and for \emptyset >1, the combustion is in the rich region, where there are excess of fuels.

3.4 Equipment and Apparatus

In this section, list of equipment used in the experiment was shown with their specifications.

3.4.1 Multimeter

Figure 3-4 Instek GDM-394 Multimeter

DC VOLTAGE		
Range	400mV, 4V, 40V, 400V, 1000V	
Best Accuracy	$\pm (0.8\% rdg + 1 digit)$	
Input Impedance	10ΜΩ	
AC VOLTAGE (50Hz ~ 400Hz)		
Range	4V, 40V, 400V, 750V	
Best Accuracy	$\pm(1\%$ rdg + 5 digits)	
Input Impedance	10M Ω

Power Source	Single 9V battery (6F22)	
Accessories	Test leads, Instruction manual, battery	
Dimensions & Weight	85(W) x 177(H) x 40(D) mm , Approx.330g	
CAPACITANCE		
Range	40nF, 400nF, 4 µ F, 40 µ F,100uF	
Best Accuracy	$\pm(3\%$ rdg + 5 digits)	
FREQUENCY		
Range	10Hz ~ 10MHz	
Best Accuracy	$\pm (0.1\%$ rdg + 3digits)	
Temperature(°C)		
Range	-40°C~1000°C	
Best Accuracy	±1%+3	

3.4.2 Thermal Imager

Resolution	0.1m/s, 0.3km/h, 19ft/min, 0.2mph, 0.2Knots			
Threshold	0.1m/s, 0.3km/h, 39ft/min, 0.2mph, 0.1Knots.			
Accuracy	+/- 5%.			
Air Temperature				
Range	-10°C ~ +45°C, 14°F~ 113°F.			
Resolution	0.2°F, 0.36°F			
Accuracy	±2°C, ±3.6°F			
Thermometer	NTC Thermometer.			
Operating	-10°C ~ +45°C (14°F~ 113°F)			
Temperature				
Operating Humidity	ng Humidity Less than or equal to 90% RH			
Storage Temperature	$-40^{\circ}\text{C} \sim +60^{\circ}\text{C}, -40^{\circ}\text{F} \sim 140^{\circ}\text{F}$			
Current Consumption	t Consumption About 3mA.			
Powered by	ed by 3V CR2032 Battery			
Dimensions	10.7cm x 4.5cm x 2.1cm - 4.21inch x 1.77inch x 0.83inch.			

3.4.4 Thermoelectric Module

Figure 3-7 Thermoelectric Module

A Thermoelectric (TE) module is an electronic component which based on semiconductor that function either by using electricity or to produce electricity. By consuming electricity, a thermoelectric module is able to move heat from a hot junction to the cold juntion of the semiconductor. In reverse, the thermoelectric module can produce electricity by using heat difference between the hot and cold junction. This occur due to the free electron that contains within the p and n junction of the module. Upon receiving heat at the hot junction, these electron will travel to the opposite site of the cold junction. These movement of electrons generate electricity thorughout the thermoelectric module. In this experiment, the thermoelectric module is couple with heat sink that consists of fins. This is to obtained the maximum heat difference between the hot and cold junction.

3.5 ANSYS Simulation.

Overall, simulating the combustion involves the process of creating geometry, meshing up the geometry, setup of the combustion processes, run calculation and finally interpretation of the results obtained. In this work, ANSYS Fluent was used as it was compatible for computational fluid dynamics calculations. ANSYS program that was used was the ANSYS 2019 R1 Academic Version.

First step taken was to import the geometry into ANSYS. The geometry of the combustor model was design in the SolidWorks program.

Figure 3-8 SolidWorks model of the combustor chamber

Next, the model was meshed. Meshing was done with the settings show in Figure 3-9 below. High smoothing option for the mesh in the quality section was also selected.

Defaults	
Physics Preference	CFD
Solver Preference	Fluent
Element Order	Linear
Element Size	Default (3.2016e-002 m)
Export Format	Standard
Export Preview Surface Mesh	No
